

## Number Theory

### ⇒ Modular Arithmetic

$$\textcircled{1} \quad (a+b) \% m = ((a \% m) + (b \% m)) \% m$$

$$\textcircled{2} \quad (a * b) \% m = ((a \% m) * (b \% m)) \% m$$

$$\textcircled{3} \quad (a - b) \% m = ((a \% m) - (b \% m) + m) \% m$$

$$\textcircled{4} \quad (b/b) \% m = ((a \% m) * (b^{-1}) \% m) \% m$$

~~(b<sup>-1</sup>)~~  $\Rightarrow$  Multiplicative inverse

Q:- find factorial of a given no. n,  
 $0 \leq n \leq 100$ .

point the answer modulo m, where  $m = 10^9 + 7$ .

Here, the factorial value can be very very large such that it can't even fit in the long long data type.

i. It is given in questions that report your answer  $\% (10^9 + 7)$ , such that every answer will be less than  $10^9 + 7$   
if this no. can be easily fit inside the int data type.

Significance of  $10^9 + 7$ :

- very close to integer max<sup>n</sup> range.
- since, it is a prime no., I can calculate the multiplicative inverse from 1 to  $(10^9 + 7)$ .

Hence, It is an ideal choice.

// Code

```
int n; cin >> n;
int m = 1000000007;
long long fact = 1;

for (int i=2; i<=n; i++) {
    fact = (fact * i) % m;
}

return fact;
```

By using the modulo  
property  $a \times b \% m = (a \% m) \times (b \% m) \% m$ , we can  
calculate it at each iteration.

for e.g.  $5! \% m$

$$\Rightarrow (1 \times 2 \times 3 \times 4 \times 5) \% m$$

$$= ((1 \times 2 \times 3 \times 4) \% m * \underline{(5 \% m)}) \% m$$

$$\Downarrow \quad (5) \Rightarrow 2 + 5 = 120 \quad \underline{\underline{=}}$$

$$((1 \times 2 \times 3) \% m * \underline{(4 \% m)}) \% m$$

$$\Downarrow \quad (4) \quad 6 \times 4 = 24$$

$$((1 \times 2) \% m * \underline{(3 \% m)}) \% m$$

$$\Downarrow \quad (3) \quad \Rightarrow 2 \times 3 = 6$$

$$((1 \% m) * \underline{(2 \% m)}) \% m$$

$$(1) \times (2) = 2$$

Hence,  $120 \% m = 120$  (answer)

## $\Rightarrow$ Binary Numbers & Bit Basics

0	$\rightarrow$	0		
1	$\rightarrow$	01		
2	$\rightarrow$	10		
3	$\rightarrow$	11		
4	$\rightarrow$	100		
5	$\rightarrow$	101		• Last LSB of every odd no. is '1'.
6	$\rightarrow$	110		
7	$\rightarrow$	111		• LSB of every even no. is '0'.

A	B	AND	OR	XOR
0	0	0	0	0
0	1	0	1	1
1	0	0	1	1
1	1	1	1	0

AND  $\rightarrow$  &

NOT  $\rightarrow$  !

OR  $\rightarrow$  |

left shift  $\rightarrow$  <<

XOR  $\rightarrow$  ^

Right shift  $\rightarrow$  >>

$$3 << 2 \Rightarrow 1100$$

$$3 >> 1 \Rightarrow 01$$

In general  $\Rightarrow$

$$x << i \quad (= x * 2^i)$$

$$x >> i = \frac{x}{2^i}$$

We can store a max of 32 bits in an integer data type.

for 4 bits, max<sup>m</sup> no. formed can be:-

$$\begin{array}{r} 1111 \\ \Rightarrow 2^4 - 1 \end{array}$$

$$\therefore \text{max}^m \text{ no. formed by 32 bits is:}-$$

$$\underbrace{1111 \dots 1}_{\text{32 times}} = 2^{32} - 1$$

\* Trick to calculate power of 2 -

$$1 \ll 0 = 2^0 = 1$$

$$1 \ll 1 = 2^1 = 2$$

$$1 \ll 2 = 2^2 = 4$$

$$1 \ll 3 = 2^3 = 8$$

$$\boxed{1 \ll n = 2^n}$$

$$\rightarrow \text{Value of INT\_MAX} = 2147483647$$

Signed

In integer, we can store  $2^{31} - 1$  nos bcz one bit is reserved for sign.

But in unsigned integer, we can store  $2^{32} - 1$  numbers.

Page \_\_\_\_\_

7	6	5	4	3	2	1	0
1 0 0 1 1 0 1 1							
↑				↑			
				MSB			LSB

Set bit  $\rightarrow$  If any bit is 1

Unset bit  $\rightarrow$  " " " " 0.

\* How to check if any bit is set or unset

e.g.  $\rightarrow$  0 0 0 1 0 1 1

Check if 3<sup>rd</sup> bit is set or not.

Take such a no. such that its 3<sup>rd</sup> bit is set & others are unset.

$\rightarrow$  0 0 0 1 0 0 0

Now, AND both these nos.

$$\begin{array}{r} \rightarrow 0 0 0 1 0 1 1 \\ + 0 0 0 1 0 0 0 \\ \hline 0 0 0 1 0 0 0 \end{array}$$

After AND, this bit is 1, i.e., the 3<sup>rd</sup> bit of original no. is set;

If it is 0, then that bit is unset

- How to find that particular bit, when we are ANDing -

that no. is  $(1 \ll i)$  for i<sup>th</sup> bit.

for checking 1<sup>st</sup> bit we will take a no., 1, i.e.,  $1 \ll 1 = 10$

for checking 2<sup>nd</sup> bit, the no. will be  $1 \ll 2 = \underline{\underline{100}}$

\* If I subtract 1 from a no. which is power of 2, then, I get a no. which consists of all 1's and 1 bit less than the original no.

$$\begin{array}{r} 100 \\ - 1 \\ \hline 11 \end{array} \quad \begin{array}{r} 1000 \\ - 1 \\ \hline 111 \end{array} \quad \begin{array}{r} 10000 \\ - 1 \\ \hline 1111 \end{array}$$

// Code for checking set bit & not set bit

```
int a=9;
int i=3;
if ((a & (1<< i)) != 0) {
    cout << "set bit";
}
else {
    cout << "Not set bit";
}
```

$\Rightarrow \cancel{0}0001001$

& 00001000

$\overbrace{00001000} \rightarrow$  i.e., 3<sup>rd</sup> bit of  
'9' is set bit.

\* To set a bit at  $i^{th}$  position

int  
~~a = 7;~~ 7;

int i = 3;

for setting 3<sup>rd</sup> bit as set, do  
~~a OR (1 << i)~~

$\rightarrow 00000111$

~~OR~~  $000001000$

$\overline{00001111} \Rightarrow$

$[a | (1 << i)]$

$\rightarrow$  To unset a bit at  $i^{th}$  position

$\sim$  (complement operator)

if  $a = 00001011$

then,  $\sim a = 11110100$

For unsetting 1 to 0, then find  
~~a no.~~ such that all other bits  
are 1 and that particular  $i^{th}$  bit is 0.  
such that ANDing 'a' and that no.  
will unset the  $i^{th}$  bit.

unset the 3<sup>rd</sup> bit.

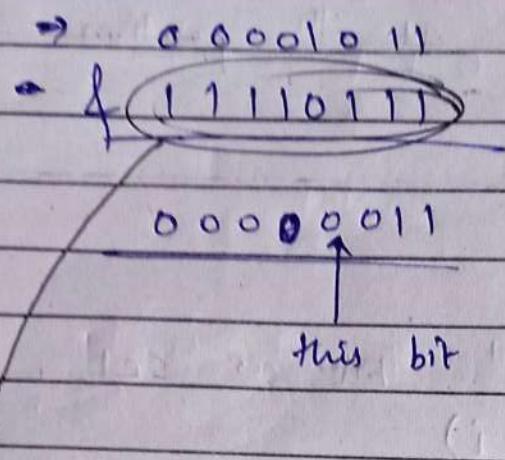

so, the required no. for ANDing is:-

11110111

↑

its 3<sup>rd</sup> bit is zero

and all other bits are 1, so that  
other bits will be preserved &  
3<sup>rd</sup> bit will be unset.

How to get this no.

$$1 \ll 3 = 00001000$$

now,  $\sim(1 \ll 3) = 11110111$

$\rightarrow$  To unset a bit, just do:

$$\boxed{a \& (\sim(1 \ll i))}$$

$\rightarrow$  toggle a bit (change  $i^{\text{th}}$  bit from 0 to 1 or 1 to 0).  
 If any bit is 0  $\rightarrow$  change it ~~to~~ 1.  
 " " 1  $\rightarrow$  " " 0.

For toggling any bit, XOR the number with such a no. that its  $i^{\text{th}}$  bit is 1 & others are zero.

bcz, we know  $0 \wedge 1 = 1$   
 and  $1 \wedge 1 = 0$

so, if the  $i^{\text{th}}$  bit is 0, XORing it with 1 toggle it to 1 & vice versa.

That particular no. is  $(1 \ll i)$ .

$$a = 9 = 00001001$$

$$i = 2 \Rightarrow \underbrace{00000100}$$

XOR  $\Rightarrow$

$$\underline{00001(101)}$$

2<sup>nd</sup> bit is toggled  
from OFF to ON.

$$a \wedge (1 \ll i) \Rightarrow \text{for toggling}$$

$\Rightarrow //$  To find bit count

Bit count is the no. of set bits in a binary no.

For every bit, we check if the bit is set or not, then do count++.

```
int count = 0;
```

```
for (int i=31; i>=0; i--) {
```

```
    if ((a & (1<<i))) != 0) {
```

```
        count++;
```

```
}
```

```
}
```

```
cout << count;
```

→ checking for set bit

## II Built-in function for counting set bit

-- builtin\_popcount(a);  $\rightarrow$  works for integers only.

-- builtin\_popcountll ((1LL << 35)-1);

$\hookrightarrow$  works for long long

## II Decimal to binary

let's say we have to represent the no. in 8 bits binary.

```
{ for (int i = 7; i >= 0; i--) {  
    cout << ((num >> i) & 1);  
}
```

{ if num = 10 , then binary  $\Rightarrow$  00001010 .

$\rightarrow$  Using this method, we can also count the set bits.  
instead of ~~count~~

```
for (int i = 7; i >= 0; i--) {  
    count += ((num >> i) & 1);  
}
```

⇒ // How to check even or odd.

0 0 0 → even

0 0 1 → odd

0 1 0 → even

0 1 1 → odd

1 0 0 → even

1 0 1 → odd

1 1 0 → even

1 1 1 → odd.

Here, we can see that, ~~even~~ the 0<sup>th</sup> bit  
or LSB of every odd no. is 1 if  
even no. is 0.

so, by doing  $(\text{num} \& 1)$  we can get either  
0 or 1.

0 indicating even no. if 1 is odd no.

```
11 if (num & 1) {  
    cout << odd;  
}  
else {  
    cout << even;  
}
```

$(\text{num} \& 1)$  is actually faster than  
 $(\text{num} \% 2 == 0)$  for checking even or  
odd.

Basically,  $\&$  / and  $\%$  operators are  
slow than bit wise operators.

→ Divide by 2:-

We know,  $n \gg i = \frac{n}{2^i}$

now, instead of doing  $(n/2)$  we can do  $(n \gg 1)$  i.e, equal to  $n/2$

since, bitwise operators are faster, so use this.

→ Upper Case & lower Case conversion using bit manipulation.

Let's see the pattern b/w uppercase & lowercase letters

A → 00001000001

a → 00001100001

B → 000010000010

b → 000011000010

C → 00001000011

c → 00001100011

D → 00001000100

d → 00001100100

E → 00001000101

e → 00001100101

The pattern b/w any uppercase & lowercase letter is  $\rightarrow$  "the 5<sup>th</sup> bit of uppercase letter is unset while that of lowercase letter is set".

- \* To convert uppercase to lowercase, set the 5<sup>th</sup> bit
- \* To convert lowercase to uppercase, unset the 5<sup>th</sup> bit

char A = 'A';

char a = A | (1<<5);  $\Rightarrow$  a  
set the 5<sup>th</sup> bit

char x = 'x';

char X = x & (~ (1<<5));  $\Rightarrow$  X  
unset the 5<sup>th</sup> bit

$\rightarrow$  Instead of doing  $1<<5$ , we can find which character is at ASCII value  $1<<5$ .

g.

char(1<<5) = ' ' (space).

so, if we OR then uppercase character & space, then we get the corresponding lowercase letter.

char a = ('A' | ' ');  $\Rightarrow$  a

$\rightarrow$  ~~for~~ we can't find  $\sim(1<<5)$  bcz it is out of range of characters.  
~~1<<5~~

But we can do a modification here

We know,  $C = 'c' \& (\sim(1 << 5))$

i.e.,  $00001\cancel{0}0001$

$\& \underline{111101111}$

Instead of this, we can say that

we need  $000101111$ , bcz ~~the~~  
all other zeroes after the left most

'1' will always be going to '0', so  
rather than taking  $111101111$ , we can  
only take  $0000101111$ .

And char value of this no. is  
(underscore) '\_'

So, simply AND the lower case letter  
and '\_' (underscore) to get the corresponding  
upper case letter.

cout << char('c' & '\_');  $\Rightarrow C$

~~\*/~~

\* To convert upper to lower  $\Rightarrow \text{char}('A' | '')$ ;

\* To convert lower to upper  $\Rightarrow \text{char}('a' \& '_')$ ;

$\Rightarrow$  Clear LSB's

$$n = 00000111011$$

Let's say upto 4<sup>th</sup> bit from LSB, we have to clear all bits.

To do so,

$$\begin{array}{r} 00000111011 \\ \text{if } 11111100000 \end{array}$$

$\rightarrow$  I need to AND ~~n~~ n with this no.

To get this no.,

I can invert 00000011111

We know,  $2^i - 1$  will a no. which has all bits 1 if has a total of  $(i-1)$  bits as '1'.

So, to get 11111 we can do  $2^5 - 1$   
i.e.,  $(2 \ll 5) - 1$ .

$$\text{i.e., } 00000011111 = (1 \ll 5) - 1$$

$$\text{and, } 11111100000 = \sim((1 \ll 5) - 1)$$

$\downarrow$   
we have to AND this no. with n, to clear all LSB's upto 4<sup>th</sup> bit.

So, to clear upto  $i$ th bit from LSB :-

$$\boxed{(n \& (\sim(1 \ll (i+1))) - 1)}$$

if  $i=4$ , and  $n = 00000111011$   
the off will be  $\Rightarrow 00000100000$

all bits upto 4<sup>th</sup> bit  
has cleared.

→ Clear MSBs

Clear all the MSB's upto  $i$ th bit.

Let  $i=3$ ,

~~then~~,

$$n = 00000\underset{\downarrow}{1}11011$$

clear all these  
to zero

So, I need to <sup>do</sup> AND ~~111~~  $00000001111$

such that:-

$$\begin{array}{r} 00000111011 \\ \& 00000001\cancel{1} \\ \Rightarrow 00000001011 & \rightarrow \text{Required answer} \end{array}$$

How to get  $00000001111$

Same as before  $\Rightarrow 0000001000 - 1$   
i.e.,  $(1 \ll 4) - 1$   
i.e.,  $(1 \ll (i+1)) - 1$ .

so, the required answer will be:-

$$n \& ((1 \ll (i+1)) - 1)$$

$\Rightarrow$  then check for any number if it is a power of 2 or not

Any power of 2 will be like this:-

$$n = 00100000$$

If we do AND with  $(n-1)$ , then it will be always zero, becz,  $(n-1)$  will be like:- 00011111

$$n \Rightarrow 00100000$$

$$\& (n-1) \Rightarrow \underline{00011111}$$

00000000  $\Rightarrow$  if it is zero, then 'n' is power of 2, else not.

11 if ( $n \& (n-1)$ ) {

} cout << "Not power of 2";

else {

} cout << "Power of 2";

$\Rightarrow$  Swap 2 no's using XOR

\* Important property of XOR

$$x \wedge x = 0$$

$$x \wedge 0 = x$$

\* XOR is associative:-

$$x \wedge (y \wedge z) = y \wedge (x \wedge z) = z \wedge (x \wedge y)$$

\* XOR is commutative:-

$$x \wedge y = y \wedge x$$

e.g.  $a = 4, b = 6.$

Step 1  $\rightarrow a = a \wedge b$

Step 2  $\rightarrow b = b \wedge a$  ||  $b = a$

$$\begin{aligned} & \downarrow \\ & \text{|| } b = b \wedge (a \wedge b) \\ & = b \wedge b \wedge a \\ & = 0 \wedge a \\ & = a \end{aligned}$$

Step 3  $\rightarrow a = a \wedge b$

$$\begin{aligned} & \hookrightarrow a = ((a \wedge b) \wedge a) \\ & = a \wedge b \wedge a = a \wedge a \wedge b \\ & = 0 \wedge b = b \end{aligned}$$

$\text{|| } a = b$

Hence, two values has been swapped.

~~Q:-~~ Given array A of n integers. All integers  
are present in even count except one.

Find that one integer which has odd  
count in  $O(N)$  time complexity &  $O(1)$  space.

Sol → Let's suppose the array is :-

2 4 6 7 7 4 2 2 2

Here, we can see that 2, 4, & 7 have even no. of count in the array  
except 6.

If we XOR all the elements, then the paired elements will cancel out each other  
(as  $x \wedge x = 0$ ) & at last 6 will be  
the answer.

// code

```
int n; cin >> n; int x;  
int ans = 0;  
for (int i = 0; i < n; i++) {  
    cin >> x;  
    ans ^= x;  
}  
cout << ans;
```

$$T \geq O(n)$$

$$S \geq O(1)$$

## ⇒ Bitmasking

Suppose there are 4 fruits.

Apple	→ 0	Representation of fruits by no's
Orange	→ 1	
Banana	→ 2	
Lichi	→ 3	

There are 3 children (let say).

Child - 1 → 2, 3	] who have Represents which fruit. is present
Child - 2 → 0, 1, 2	
Child - 3 → 1, 3	

If we store the choices of fruits of different children in different arrays then it is time & space taking. Furthermore, if we are to find the union & intersection, then it take  $O(n)$  time.

To reduce this space & time, we use bit mask.

Child - 1 → 2, 3.

For the preferences 2 & 3, we can generate such a binary no., so that its 2<sup>nd</sup> & 3<sup>rd</sup> bit are set.

e.g., 1100

Child - 2 → 0, 1, 2 → 0111

Child - 3 → 1, 3 → 1010

1 represents the preference of child.

Now, if we wish to find intersection, i.e., common fruits b/w child 1 & 2, the simply do AND operation b/w child-1 & 2.

i.e., 1100

$$\begin{array}{r} \text{f} \\ \text{0111} \\ \hline \text{0100} \end{array}$$

$\Rightarrow$  It is clear that the 2nd fruit is common b/w child-1 & child-2.

If we want to find union, then do OR.

1100

$$\begin{array}{r} \text{or} \\ \text{0111} \\ \hline \text{1111} \end{array}$$

Time  $\rightarrow O(1)$

Space  $\rightarrow O(1)$

But this technique only works for small ranges.

b/cz range of integer = 32 bit  
 " " long long = 64 bit.

we can't represent more than 64 items using bit mask.

Q:- There are  $N \leq 5000$  workers. Each worker is available for some days of this month (30 days). For each worker, given a set of no's in the interval [1, 30] representing his/her availability. Find two workers that are best for the job - maximize the no. of days when both these are available.

→ Input:  
n → no. of workers  
days → for each worker, how many days he/she is working  
a[days] ↴ array representing on which days he/she is working

```
int n;  
cin >> n;  
vector<int> masks(n, 0); // This vector will  
for(int i=0; i<n; i++) {  
    int num-workers;  
    cin >> num-workers;  
    int mask = 0;  
    for(int j=0; j< num-workers; j++) {  
        int day;  
        cin >> day;  
        mask = (mask | (1 << day));  
    }  
    mask[i] = mask;
```

This loop  
will convert  
every day input  
into bit-mask.

```

int max_days = 0;
int person1 = -1, person2 = -1;
for (int i=0; i<n; i++){
    for (int j=i+1; j<n; j++){
        int intersection = (masks[i] & masks[j]);
        int common_days = __builtin_popcount(intersection);
        if (common_days > max_days)
            max_days = common_days;
        person1 = i;
        person2 = j;
    }
}

```

This will output  
 the two persons  
 whose intersection  
 is maximum  
 and are common  
 days b/w them.

cout << person1 << " " << person2 << " " << max\_days << endl;

## Subset Generation b/w bitmasking

Let suppose an array  $\rightarrow [2, 3, 7, 8, 9]$

To represent this array as a bitmask, we need 5 bits, bcz there are 5 elements & each index can be represented by a bit.

If we choose the subset:-  
 $[3, 8]$

then it can be represented by 01010.  
 which  $\rightarrow$  In this bit mask, 3rd & 1st bit are set, which means, the 3rd & 1st index elements are part of the array are present in the subset.

eg.  $\text{arr} = [2, 4, 5]$

Total no. of subset =  $2^n$  ( $n \Rightarrow$  size of array)

$$2^3 = 8 \text{ subsets}$$

[ ], [2], [4], [5], [2, 4], [2, 5], [4, 5],  
[2, 4, 5]

These 8 subsets can be represented by  
000 - 111, where the set bit represent  
that index of array of which element is  
present in subset.

0	$\rightarrow 000$	[ ]	
1	$\rightarrow 001$	[2]	// 1st arr element
2	$\rightarrow 010$	[4]	0 <sup>th</sup> index of array
3	$\rightarrow 011$	[2, 4]	present here, i.e., arr[0].
4	$\rightarrow 100$	[5]	
5	$\rightarrow 101$	[2, 5]	↓. Similar all <u>bitmasks</u>
6	$\rightarrow 110$	[4, 5]	
7	$\rightarrow 111$	[2, 4, 5]	

|| code (input = [2, 4, 5] (arr).)

```
int n = arr.size();
int subset_count = (1 << n); //  $2^n$  subsets.
vector<vector<int>> subsets;
```

```
for (int i=0; i< subset_count; i++) {
    vector<int> v;
    for (int j=0; j< n; j++) {
        if ((i & (1 << j)) != 0) {
            v.push_back(arr[i]);
        }
    }
    subsets.push_back(v);
}
return subsets;
```

We have 8 possibilities from 000 to 111.  
for every possibility, we are checking that  
which bit is set, & if ith bit  
is set, then push the arr[i] in the  
vector. (i.e., subset is created)

Now, push this subset into the 2-D array  
i.e., array of subsets.

$$T = O(n \times 2^n)$$

$\Rightarrow$  GCD and LCM

~~GCD~~  $12 \rightarrow 2^2 \times 3^1$   
 $18 \rightarrow 2^1 \times 3^2$

$$\begin{aligned} GCD &= \text{minimum of powers of prime factors.} \\ &= \min(2^2, 2^1) * \min(3^1, 3^2) \\ &= 2 \times 3 = 6 \end{aligned}$$

$$\begin{aligned} HCF &= \text{maximum of powers of prime factors} \\ &= \max(2^2, 2^1) * \max(3^1, 3^2) \\ &= 2^2 \times 3^2 = 36 \end{aligned}$$

$$\boxed{GCD * HCF = \text{product of numbers}}$$

→ GCD by long division method/Euclid's Algo

e.g.  $\underline{18} \div \underline{12}$

$$\begin{array}{r} 12 \quad | \quad 18 \quad | \quad 1 \\ \underline{12} \\ (B) \quad | \quad 12 \quad | \quad 2 \\ \checkmark \quad | \quad 12 \quad | \quad 2 \\ GCD \quad | \quad 0 \end{array}$$

\* Continuously divide until remainder becomes zero.

e.g.  $\underline{13} \div \underline{7}$

$$\begin{array}{r} 7 \quad | \quad 13 \quad | \quad 1 \\ \underline{7} \\ 6 \quad | \quad 7 \quad | \quad 1 \\ \checkmark \quad | \quad 6 \quad | \quad 1 \\ (D) \quad | \quad 6 \quad | \quad 1 \\ \checkmark \quad | \quad 6 \quad | \quad 1 \\ GCD \quad | \quad 0 \end{array}$$

If rem. is not zero then make the rem. as divisor of previous divisor as dividend & continue further.

The final divisor will be the GCD

// Code  
int gcd (int a, int b) {

// If the remainder is zero, then return divisor, else we can say, if divisor is zero, then return dividend.

// otherwise, in the next division, the dividend will be the prev. divisor, i.e., 'b' and divisor will be the remainder of current dividend of divisor, ie.,  $a \% b$ .

```

if (b == 0) {
    return a;
}
else
{
    return gcd(b, a % b);
}

```

$$\text{lcm} \Rightarrow (a * b) / \text{gcd}(a, b);$$

Inbuilt function for GCD  $\Rightarrow \text{--gcd}(a, b);$   
 $T \Rightarrow (\log n)$

$\Rightarrow$  gcd of three no's  $\Rightarrow \text{--gcd}(\text{--gcd}(a, b), c);$

\* find min<sup>m</sup> fraction of a fb.

e.g.  $\frac{12}{18}$   $\stackrel{2}{\cancel{\frac{12}{18}}} = \frac{2}{3}$  is the min<sup>m</sup> fraction

so, to achieve this, divide a fb by  
 their gcd.

i.e., 
$$\frac{a}{b} = \frac{a/\text{gcd}(a, b)}{b/\text{gcd}(a, b)}$$

### Bit manipulation

Q:- Given  $n$ , print the XOR of all nos below  $1^{\text{st}}$  if's.

Let  $n = 8$

$n=1$

$n=2$

$n=3$

$n=4$

$n=5$

$n=6$

$n=7$

$n=8$

XOR:	
1	$(0 \wedge 1)$
3	$(1 \wedge 2)$
0	$(1 \wedge 2 \wedge 3)$
4	$(0 \wedge 1 \wedge 2 \wedge 3 \wedge 4)$

XOR:	
1	$(3 \wedge 4)$
7	$(5 \wedge 6)$
0	$(7 \wedge 8)$
8	$(1 \wedge 2 \wedge \dots \wedge 8)$

There is pattern of 4 groups

if  $(n \% 4 == 0)$

then answer will always be n.

i.e., for 4, 8, 12, 16, ...

if  $(n \% 4 == 1)$

answer = ~~(n+1)~~ 1

clearly we can see, for  $n=1, 5, 9, \dots$   
ans = 1.

if  $(n \% 4 == 2)$

ans =  $n+1$

$$\boxed{T = O(1)}$$

if  $(n \% 4 == 3)$

ans = 0

Q:- Given a range  $[L, R]$ , point the XOR of all elements, i.e.,  $\text{XOR}(L \wedge L+1 \wedge L+2 \wedge \dots \wedge R-1 \wedge R)$

e.g.  $[2, 4]$

$$\text{i.e., } 2 \wedge 3 \wedge 4 = 5$$

$$[3, 6] = 3 \wedge 4 \wedge 5 \wedge 6$$

$$\text{now } \text{xor}[3, 6] = \text{xor}[1, 6] \wedge \text{xor}[1, 2]$$

$$= (\cancel{1 \wedge 2 \wedge 3 \wedge 4 \wedge 5 \wedge 6}) \wedge (\cancel{1 \wedge 2})$$

Cancel out

$$\text{i.e., } \boxed{\text{xor}[l, r] = \text{xor}[1, r] \wedge \text{xor}[1, l-1]}$$

(find xor of all no's upto  $r$ )

$\Rightarrow O(1)$

(xor of all no's upto  $l-1$ )

To cancel the no's upto  $(l-1)$ , we need to xor ~~them~~ them with  $(l-r)$  bcz, xor of same no's cancel out each other.

Q :- Remove the last set bit.

e.g. 110110  
↑  
last set bit

After 1st operation, it will be: 110100  
" 2nd " " " " " 110000

for doing so, just perform:-

$$\boxed{n + n-1}$$

e.g.  $n = 13 = 1101$   $\rightarrow$  last set bit

$$\begin{array}{r} n \rightarrow 1101 \\ n-1 \rightarrow 1100 \\ \hline 1100 \end{array}$$

→ Count the no. of set bits :-

```
while ( $n \neq 0$ ) {  
    if ( $n \& 1 == 1$ ) {  
        count++;  
    }  
    n >>= 1;  
}  
cout << count;
```

(2nd method)

Turn off the set bits one by one if each time do count++.

e.g.  $n = 13$   
 $= 1101$

$$\begin{array}{r} 1101 \\ \cancel{\text{f}} \cancel{1} \\ \hline 0001 \end{array} \rightarrow \text{count} = 1$$

$n >> 1 = 0110$

$$\begin{array}{r} 0110 \\ \cancel{\text{f}} \cancel{1} \\ \hline 0000 \end{array}$$

$n >> 1 = 0011$

$$\begin{array}{r} 0011 \\ \cancel{\text{f}} \cancel{1} \\ \hline 0001 \end{array} \rightarrow \text{count} = 2$$

$n >> 1 = 0001$

$$\begin{array}{r} 0001 \\ \cancel{\text{f}} \cancel{1} \\ \hline 0000 \end{array} \rightarrow \text{count} = 3$$

$n >> 1 = 0000$

no. of set bits = 3

$$T = O(MSB)$$

i.e.,  $O(\text{position of MSB bit})$

in this case  $O(4)$

$$\begin{array}{l} 1101 \xrightarrow{\text{Turn off}} \text{count} = 1 \\ \rightarrow 1000 \\ \xrightarrow{\text{Turn off}} \text{count} = 2 \\ \rightarrow 0000 \\ \xrightarrow{\text{Turn off}} \text{count} = 3 \\ \rightarrow 0000 \quad (\text{Stop}) \end{array}$$

// Code

```
while ( $n \neq 0$ ) {  
    n = n & (n - 1);
```

```
    count++;
```

```
}
```

```
cout << count;
```

$$T = O(\text{no. of set bits})$$

There is not much difference in time complexity for both methods.

but the 2nd method is slightly optimal for certain cases.

Q2 Given an array. All integers appears twice except two which appears once. Print that two no's.

$$\text{arr} = [2, 1, 2, 5, 1, 4, 4, 7, 3, 3]$$

The xor of all elements will be :-

$$\begin{aligned} \text{xor} &= 2 \wedge 1 \wedge 2 \wedge 5 \wedge 1 \wedge 4 \wedge 4 \wedge 7 \wedge 3 \wedge 3 \\ &= 5 \wedge 7 \quad \Rightarrow 101 \\ &= \underline{\underline{(2)}} \quad \begin{array}{r} 111 \\ - 010 \\ \hline \end{array} \end{aligned}$$

This 2 indicates that ?

(The binary of 2 is 010)

Its 1st bit is set, which indicates that the 1st bit of any one is 0 if that of other is 1, so that their ~~xor~~ is 1.)

i.e., the ~~first~~ xor '010' is due to 5 & 7

$$\begin{array}{c} \overbrace{5 \quad (1^{\text{st}} \text{ bit} \\ \text{is } 0)} \\ \hline 1 \\ 5 \\ 1 \\ 4 \\ \hline 5 \end{array}$$

$$\begin{array}{c} \overbrace{7 \quad (1^{\text{st}} \text{ bit is } 1)} \\ \hline 2 \\ 2 \\ 7 \\ 3 \\ \hline 7 \end{array}$$

Now, divide the array into 2 parts such that 1st half will have those no's whose 1st bit is 0 and 2nd half will have those no's whose 1st bit is 1. And xor of those two halves individually will give the two no's that appears once.

It's bcz if any ~~no.~~ no. comes under any half then its duplicate will also comes in that half, whose XOR will be ultimately 0. & finally that no. will be the ans that appears once.

## // Code

```
xor = 0;
```

```
for (i=0 → n){
```

```
    xor = xor ^ a[i];
```

```
}
```

```
count = 0;           // It will store the index of 1st set bit of xor
```

```
while(xor != 0){
```

```
    if (xor & 1){
```

```
        break;
```

```
}
```

```
    count++;
```

```
    xor >>= 1;
```

```
}
```

// Now divide the arr into two parts

```
xor1 = 0, xor2 = 0;
```

```
for (i=0 → n){
```

```
    if (a[i] & (1 << count)) {
```

```
        xor1 = xor1 ^ a[i];
```

```
}
```

```
else {
```

```
    xor2 = xor2 ^ a[i];
```

```
}
```

```
print (xor1, xor2);
```

If the (count)<sup>th</sup> bit is set  
then put a[i] in  
1<sup>st</sup> half & take xor  
of all them else  
put a[i] in 2<sup>nd</sup>  
half & xor them  
all.

$T = O(n)$

Space = O(1).

Q:- Given  $n$  integers, print the XOR of all subsets.

$$\text{arr} = [1, 3, 2]$$

$\{\}$	$\rightarrow$	0
$\{1\}$	$\rightarrow$	1
$\{3\}$	$\rightarrow$	3
$\{2\}$	$\rightarrow$	2
$\{1, 3\}$	$\rightarrow$	2
$\{1, 2\}$	$\rightarrow$	3
$\{3, 2\}$	$\rightarrow$	1
$\{1, 2, 3\}$	$\rightarrow$	0

$$\begin{aligned}1 \wedge 2 &= 3 \\2 \wedge 3 &= 1 \\3 \wedge 1 &= 2\end{aligned}$$

cyclic

$$1 \wedge 2 \wedge 3 = 0$$

The answer will be always zero for every array bcz there are  $2^n$  subsets of  $n$  nos. If in this  $2^n$  subsets, every no. will appear even no. of times ~~totally~~ whose XOR ultimately be 0, except for the array that has only one element.

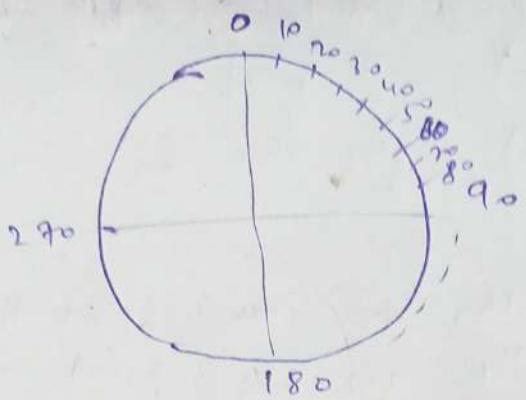

~~Final~~

Q:- There is a lock which has a scale of  $360^\circ$  & pointer at  $0^\circ$ . You have to rotate the lock's wheel exactly  $n$  times. If i<sup>th</sup> rotation should be  $a_i$  degrees either in clockwise or anticlockwise, and after all rotations the pointer should point at  $270^\circ$ . If it is possible print Yes, else No.

Constraints :-

$$1 \leq n \leq 15$$

$$0^\circ \leq a_i \leq 180^\circ$$

e.g.  $\rightarrow n=3$

$[10, 20, 30]$

if we do  $10^\circ$  clockwise  
 $20^\circ$  clockwise

& then  $30^\circ$  Ac

then we reach at  
 $0^\circ$  again. Hence point yes

\* For any given pattern of angles, one thing we can say that if the sum is divisible by  $360^\circ$ , then it will always go to  $0^\circ$  after  $n$  rotations.

\* We have to find the sum of array either rotately clockwise (+) or Ac (-).

Here,  $n=15$ , so we can use subset generation using bit mask technique.

for eg.  $\rightarrow$  arr =  $[10, 20, 30]$

no. of subsets =  $2^3 = 8$ .

	0	1	2
0	0	0	0
1	0	0	1
2	0	1	0
3	0	1	1
4	1	0	0
5	1	0	1
6	1	1	0
7	1	1	1

$1 \Rightarrow (+)$

$0 \Rightarrow (-)$

$0\ 0\ 0$  represents  $(-10 -20 -30)$   
which is not equal to zero.  
By doing similarly, for every

subset, we will reach  $110^\circ$ , where  $(10 + 20 + 30) = 60^\circ$   
& hence the answer is yes

The subsets will generate the sum for every possibility.

## // Pseudo code

~~fact~~

~~---~~

for ( $i=0$  to  $(2^n - 1)$ ) { // For  $2^n$  subsets.

    sum = 0;

    for (bits = 0 to  $(n-1)$ ) { // Checks for every bit

        if (~~==~~ i &  $(1 \ll bits)$ ) {

            sum += a[i];

        } else {

            sum -= a[i];

        }

        if ( $sum \% 360 == 0$ )

            cout << "Yes";

            break;

    }

}

// This power set method works for  $|n| \leq 16, 17, 18$ ,  
bcz after that the time limit exceeds.

## =) Bitmask

If we have ~~some~~ add or remove some elements such that no duplicates will be stored, so we need a set DS., i.e., will do in  $\log(n)$  time for space complexity.

To do it in  $O(1)$  complexity, we will use Bitmask.

~~But~~ But bit mask will store values upto  $2^{63}$  only  
bcz in long long (maxm data type), these will  
be 64 bits only ( $0 - \underbrace{63}$ ).

add (5)  $\rightarrow$  for adding 5, we will set the 5<sup>th</sup> bit  
add (1)  $\rightarrow$  set 1<sup>st</sup> bit  
add (5)  $\rightarrow$  " 5<sup>th</sup>"  
add (3)  $\rightarrow$  " 3<sup>rd</sup>"  
remove (5)  $\rightarrow$  unset 5<sup>th</sup> bit  
print  $\rightarrow$  print all the indexes of set bits

Long Long x = 0;  
add (5)  $\rightarrow$   $x \mid (1 \ll 5)$   $\rightarrow$   $\#00100000$   
add (1)  $\rightarrow$   $x \mid (1 \ll 1)$   $\rightarrow$  00100010  
add (5)  $\rightarrow$   $x \mid (1 \ll 5)$   $\rightarrow$  00100010  
add (3)  $\rightarrow$   $x \mid (1 \ll 3)$   $\rightarrow$  00101010  
remove (5)  $\rightarrow$   $x \mid (\sim(1 \ll 5))$   $\rightarrow$  00001010

print  $\rightarrow$  for ( $i \rightarrow 0$  to 63){  
    if ( $x \& (1 \ll i)$ ){  
        print (i)  
    }  
}.

//output = 1, 3
